

# ENSAR2-NUSPRASEN Workshop, HIL-Warsaw, 22-24 January 2018

## Resonant Reactions with the Trojan Horse Method

### Aurora Tumino

# **Outline**

Basic features of the Trojan Horse Method

The Trojan Horse Method for resonant reactions

Physics Case: The  $^{12}C(^{12}C, \alpha)^{20}Ne$  and  $^{12}C(^{12}C, p)^{23}Na$  reactions

# Trojan Horse Method

Basic principle: astrophysically relevant two-body  $\sigma$  from quasi-free contribution of an appropriate three-body reaction

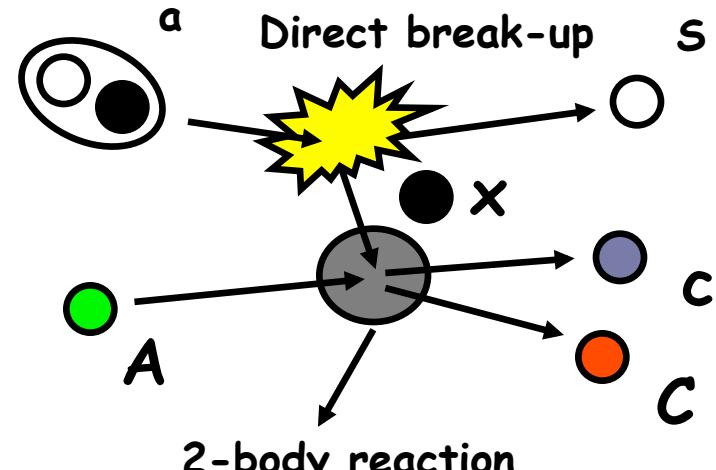

a:  $x \oplus s$  clusters

## Quasi-free mechanism

- ✓ only  $x - A$  interaction
- ✓  $s = \text{spectator}$  ( $p_s \sim 0$ )

$E_A > E_{\text{Coul}} \Rightarrow$  NO Coulomb suppression

NO electron screening

$$E_{\text{q.f.}} = E_{ax} = m_x / (m_x + m_A) E_A - B_{x-s} \quad (\pm \text{ intercluster motion})$$

plays a key role in compensating for  
the beam energy

$$E_{\text{q.f.}} \approx 0 \quad !!!$$

# Theoretical approach to the THM

PWIA hypotheses:

- $A$  does not interact simultaneously with  $x$  and  $s$
- The presence of  $s$  does not influence the  $A-x$  interaction

KF kinematical factors

$|\Phi|^2$  momentum distribution of  $s$  inside  $a$

$d\sigma^{\text{off}}/d\Omega$  Nuclear cross section for the  $A+x \rightarrow C+c$  reaction

A. Tumino et al., PRL 98, 252502 (2007)

$d\sigma^{\text{off}}/d\Omega \rightarrow d\sigma/d\Omega$  (on shell)

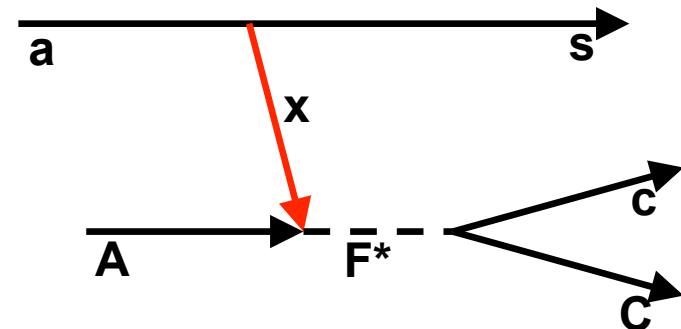

the penetration factor  $P_l$  has to be introduced:

$$\frac{d\sigma}{d\Omega} = \sum_l P_l \frac{d\sigma_l^N}{d\Omega}$$

but No absolute value of the cross section  $\rightarrow$  normalization to direct data available at higher energies

# ...for resonant reactions

The  $A + a(x+s) \rightarrow F^*(c + C) + s$  process is a transfer to the continuum where particle  $x$  is the transferred particle

Standard R-Matrix approach cannot be applied to extract the resonance parameters → Modified R-Matrix is introduced instead

In the case of a resonant THM reaction the cross section takes the form

$$\frac{d^2\sigma}{dE_{Cc} d\Omega_s} \propto \frac{\Gamma_{(Cc)_i}(E) |M_i(E)|^2}{(E - E_{R_i})^2 + \Gamma_i^2(E)/4}$$

$M_i(E)$  is the amplitude of the transfer reaction (upper vertex) that can be easily calculated  
→ The resonance parameters can be extracted

## Advantages:

- possibility to measure down to zero energy
- No electron screening
- HOES reduced widths are the same entering the OES  $S(E)$  factor (New!)

RESONANCES IN  $C^{12}$  ON CARBON REACTIONS

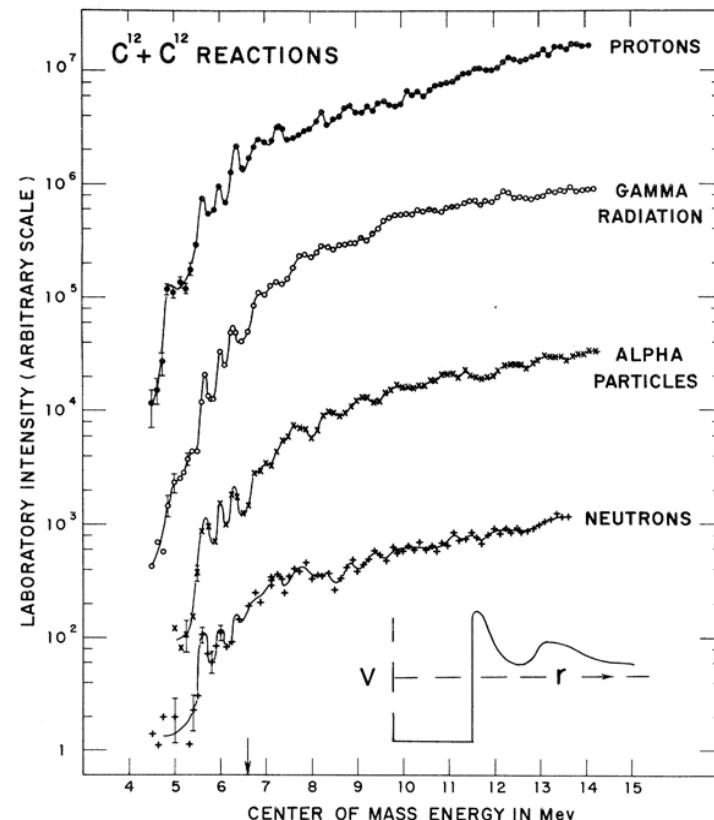

E. Almqvist, D. A. Bromley, and J. A. Kuehner

Atomic Energy of Canada Limited, Chalk River Laboratories, Chalk River, Ontario, Canada

(Received March 28, 1960)

The world's first tandem accelerator  
Installed at Chalk River in 1959

Molecular resonances in the  $^{12}C+^{12}C$   
fusion reaction

# $^{12}\text{C} + ^{12}\text{C}$ fusion

Great interest in a wide range of stellar burning scenarios in carbon-rich environments such as  
late evolutionary stages of stars with more than  $8 M_{\odot}$   
superbursts from accreting neutron stars  
Sne Ia

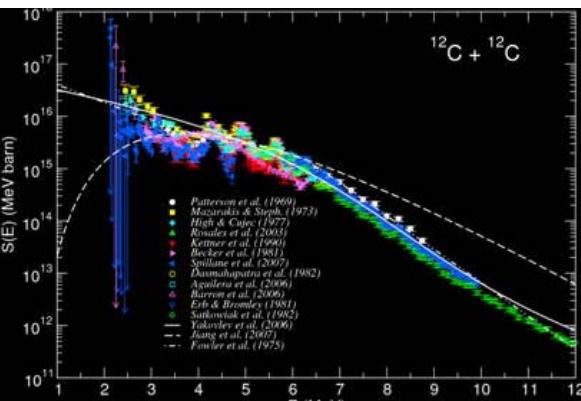

Carbon burning temperature from 0.5 to 1.2 GK  $\rightarrow E_{\text{cm}}$  from 1 to 2 MeV

Principal reactions:

$^{12}\text{C}(^{12}\text{C}, \alpha)^{20}\text{Ne}$	+ 4.617 MeV
$^{12}\text{C}(^{12}\text{C}, p)^{23}\text{Na}$	+ 2.241 MeV
$^{12}\text{C}(^{12}\text{C}, n)^{23}\text{Mg}$	- 2.599 MeV
$^{12}\text{C}(^{12}\text{C}, \gamma)^{24}\text{Mg}$	+13.933 MeV
$^{12}\text{C}(^{12}\text{C}, 2\alpha)^{20}\text{Ne}$	-0.113 MeV

} The most frequent results of the interaction

Considerable efforts to measure the  $^{12}\text{C} + ^{12}\text{C}$  cross section at astrophysical energies:

- M.G. Mazarakis & W.E. Stephensen, Phys. Rev. C 7 1280 (1973)  
K. U. Kettner *et al.*, Phys. Rev. Lett. 38, 337 (1977)

# C-burning: Status of Art

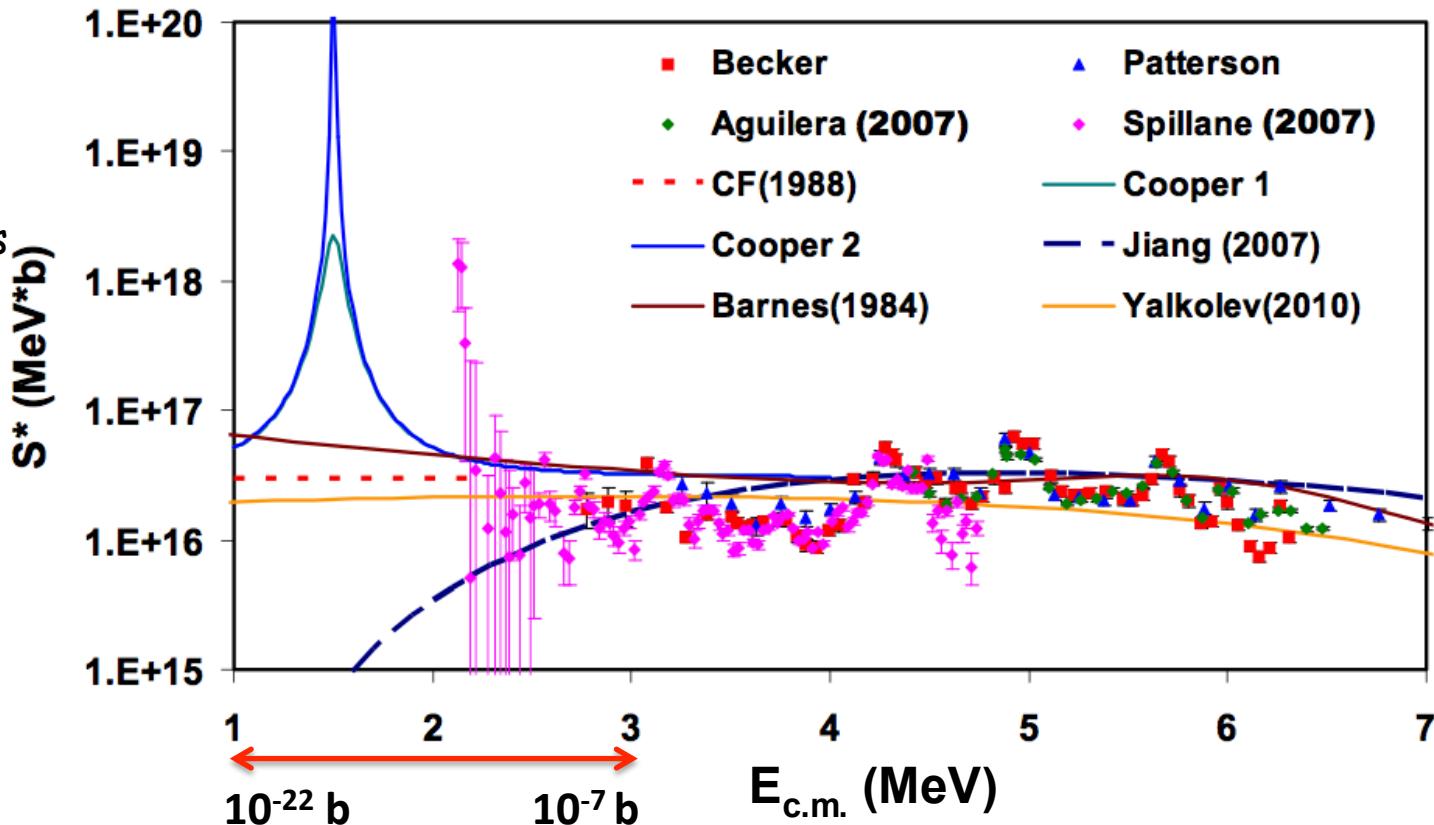

Resonances at nearly every 300 keV down to  $E_{\text{cm}} = 2.14 \text{ MeV}$ . They would increase the present nonresonant reaction rate of the alpha(proton) channel by a factor of 5(2).

extrapolations differ by  
3 orders of magnitude

large uncertainties  
in astrophysical models  
of stellar evolution  
and nucleosynthesis

$$S^*(E) = \sigma(E)E \exp\left(\frac{87.21}{\sqrt{E}} + 0.46E\right)$$

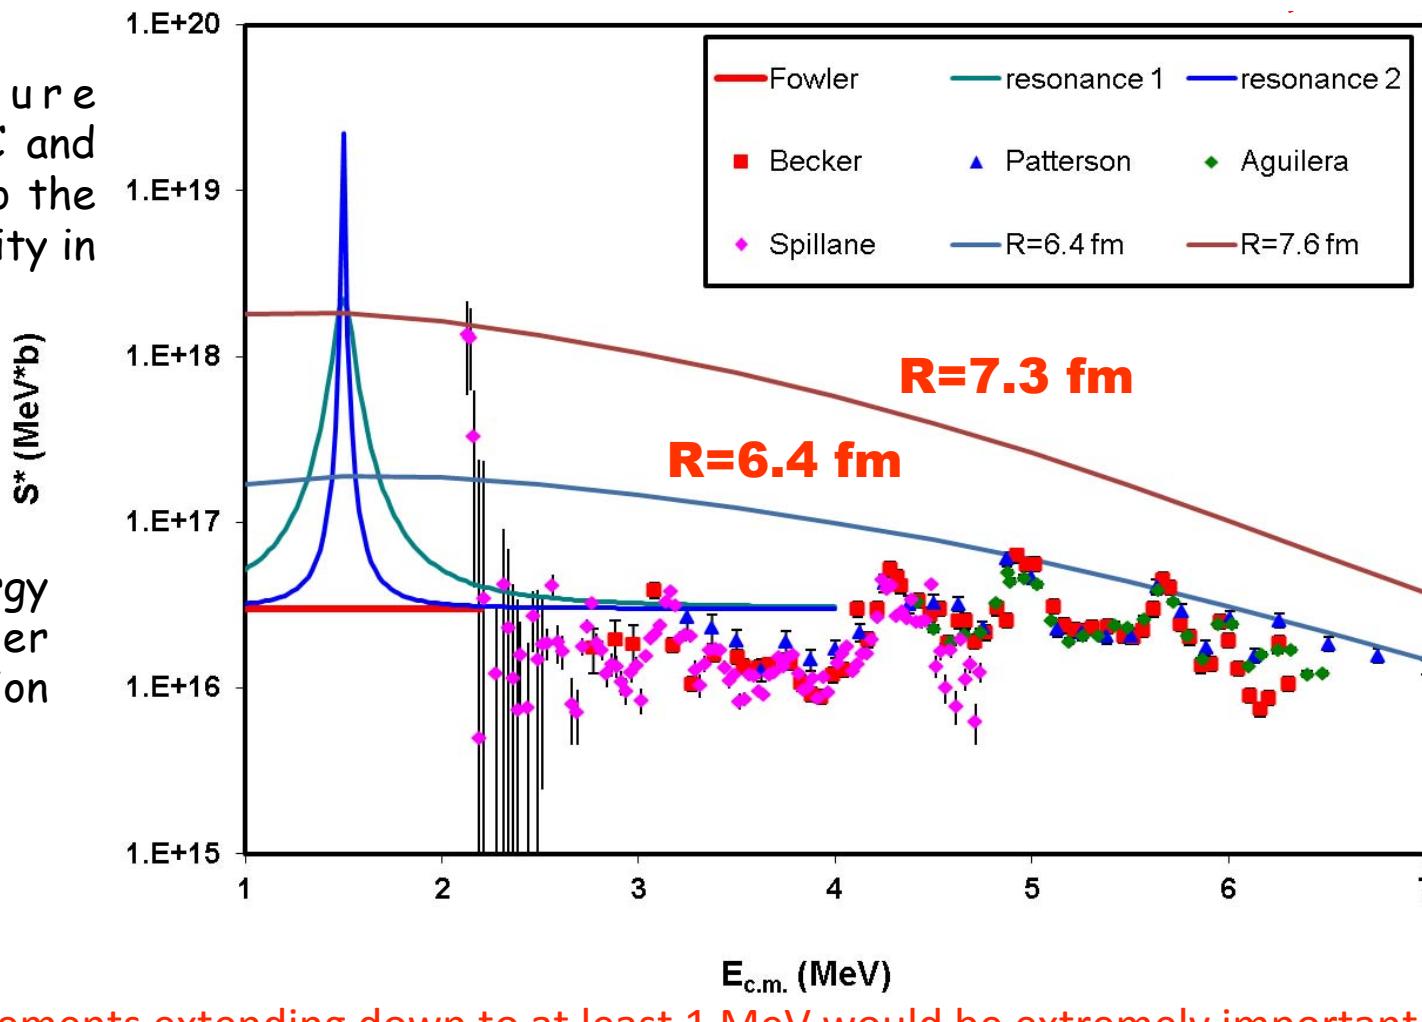

# C-burning: Status of Art

By comparing the cross sections for the three carbon isotope systems,  $^{12}\text{C}+^{12}\text{C}$ ,  $^{12}\text{C}+^{13}\text{C}$ , and  $^{13}\text{C}+^{13}\text{C}$ , it is found that the cross sections for  $^{12}\text{C}+^{13}\text{C}$  and  $^{13}\text{C}+^{13}\text{C}$  provide an upper limit for the fusion cross section of  $^{12}\text{C}+^{12}\text{C}$  over a wide energy range (M. Notani et al. PRC 85 (2012) 014607)

Resonant structure smeared in the  $^{12}\text{C}+^{13}\text{C}$  and  $^{13}\text{C}+^{13}\text{C}$  systems, due to the much higher level density in their compound nuclei.

With the lowest energy point different upper limit (change in fusion barrier parameters)

No definite conclusion!

→ Thus, further measurements extending down to at least 1 MeV would be extremely important.

# Our Experiment with the THM

$^{12}\text{C}(^{12}\text{C}, \alpha)^{20}\text{Ne}$  and  $^{12}\text{C}(^{12}\text{C}, p)^{23}\text{Na}$  reactions via the Trojan Horse Method applied to the  $^{12}\text{C}(^{14}\text{N}, \alpha^{20}\text{Ne})^2\text{H}$  and  $^{12}\text{C}(^{14}\text{N}, p^{23}\text{Na})^2\text{H}$  three-body processes  
 $^2\text{H}$  from the  $^{14}\text{N}$  as spectators

Observation of  $^{12}\text{C}$  cluster transfer in the  $^{12}\text{C}(^{14}\text{N}, d)^{24}\text{Mg}^*$  reaction

(R.H. Zurmühle et al. PRC 49(1994) 5)

## QUASI-FREE MECHANISM

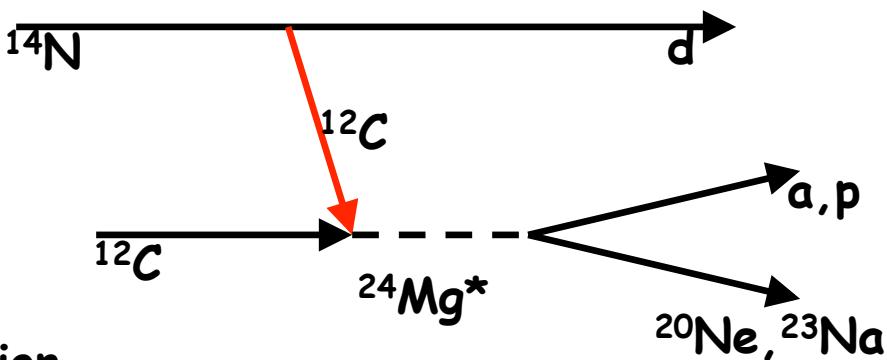

- ✓ only  $^{12}\text{C} - ^{12}\text{C}$  interaction
- ✓  $d$  = spectator

$$E_{^{14}\text{N}} = 30 \text{ MeV} > E_{\text{Coul}}$$

NO Coulomb suppression

⇒

NO electron screening

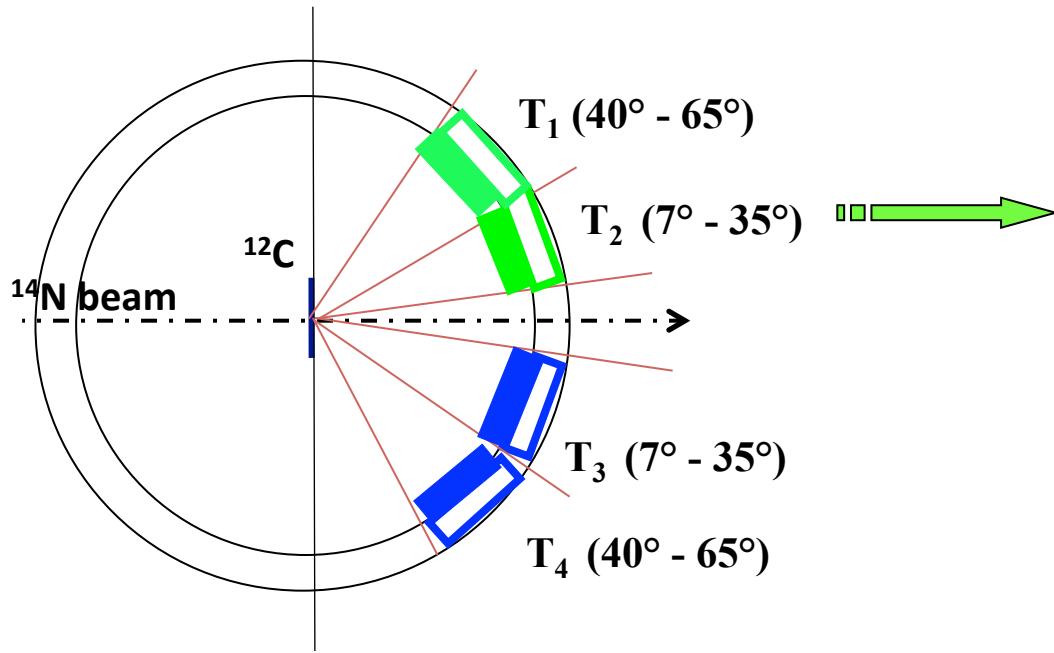

$$E_{\text{QF}} = E_{^{14}\text{N}} \frac{m_{^{12}\text{C}}}{m_{^{14}\text{N}}} \cdot \frac{m_{^{12}\text{C}}}{m_{^{12}\text{C}} + m_{^{12}\text{C}}} - 10.27 \text{ MeV}$$

# The $^{14}\text{N} + ^{12}\text{C}$ experiment at LNS

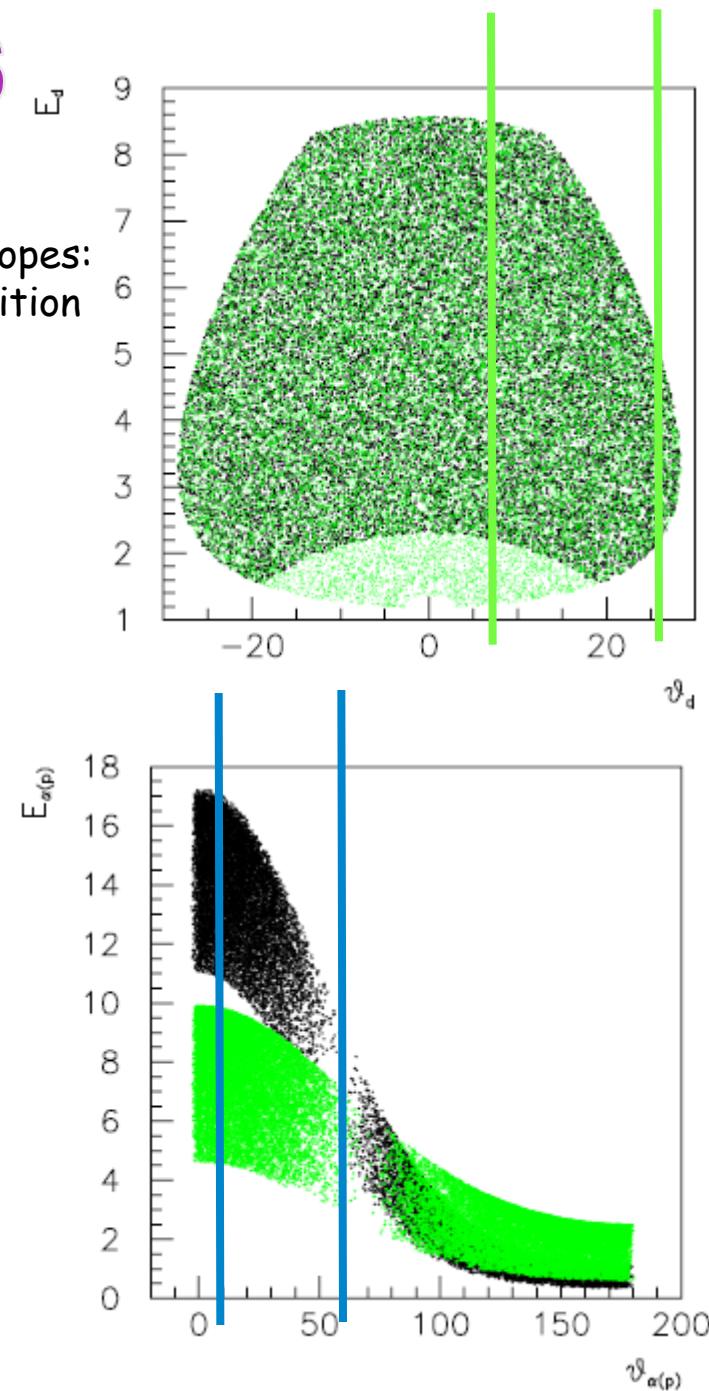

$E_{^{14}\text{N}} = 30 \text{ MeV}$

Particle identification supplied by silicon telescopes:  
 $38 \mu\text{m}$  silicon detector as  $\Delta E$ - and  $1000 \mu\text{m}$  Position Sensitive Detector (PSD) as E-detector

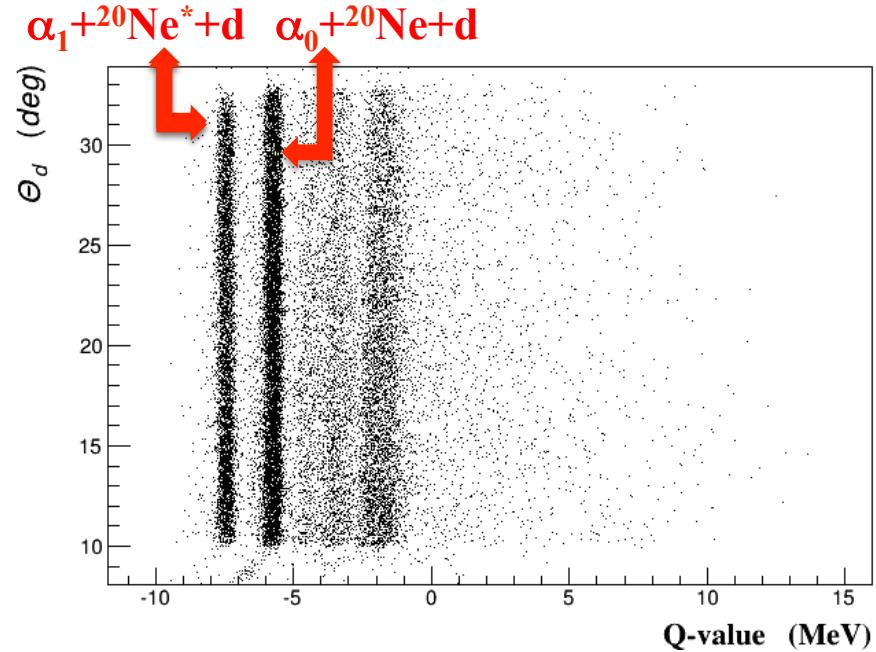

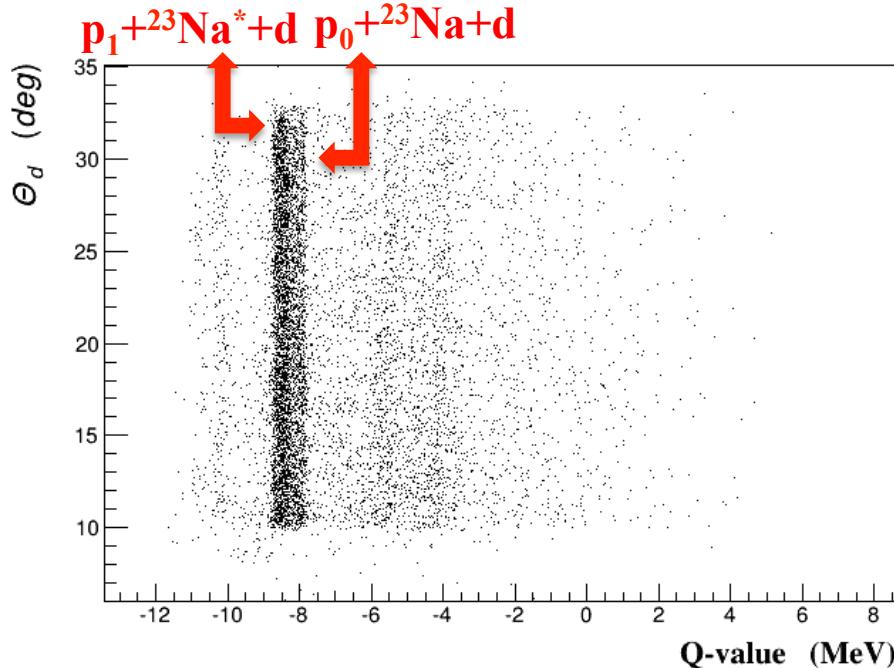

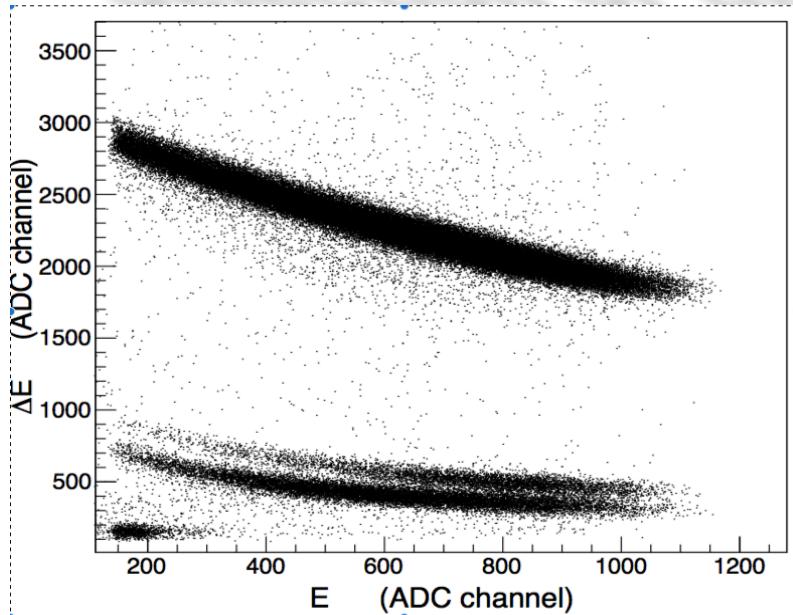

$^{20}\text{Ne} + \alpha + d$  and  $^{23}\text{Na} + p + d$  reaction channels reconstructed when detecting the ejectile of the two-body reactions (either  $\alpha$  (black dots) or  $p$  (green dots)) in coincidence with the spectator  $d$  particle.

No detection of  $^{20}\text{Ne}$  or  $^{23}\text{Na}$  quite low energy  $\rightarrow$  too high detection threshold

# Selection of the 3-body channels

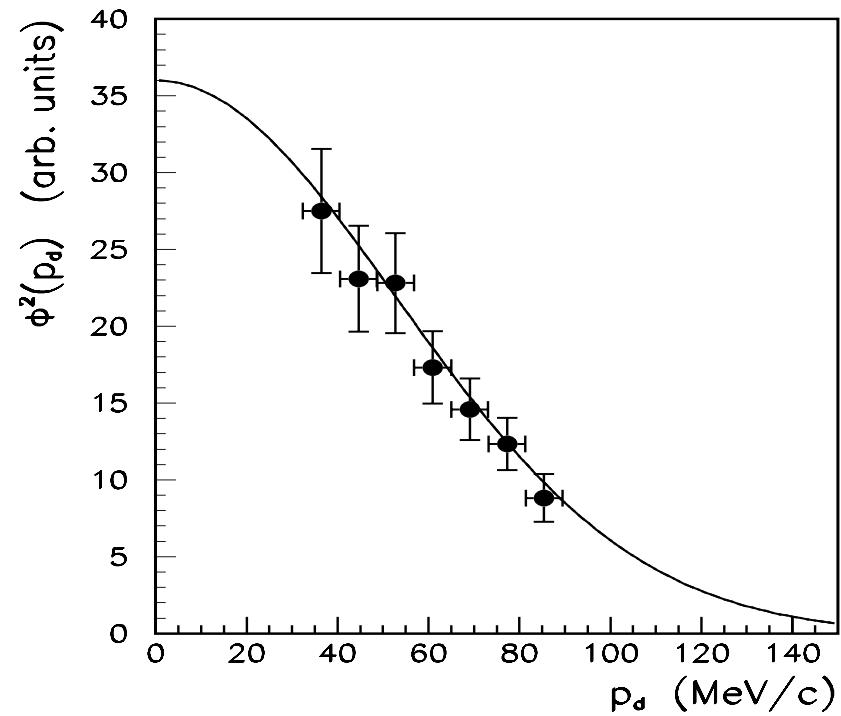

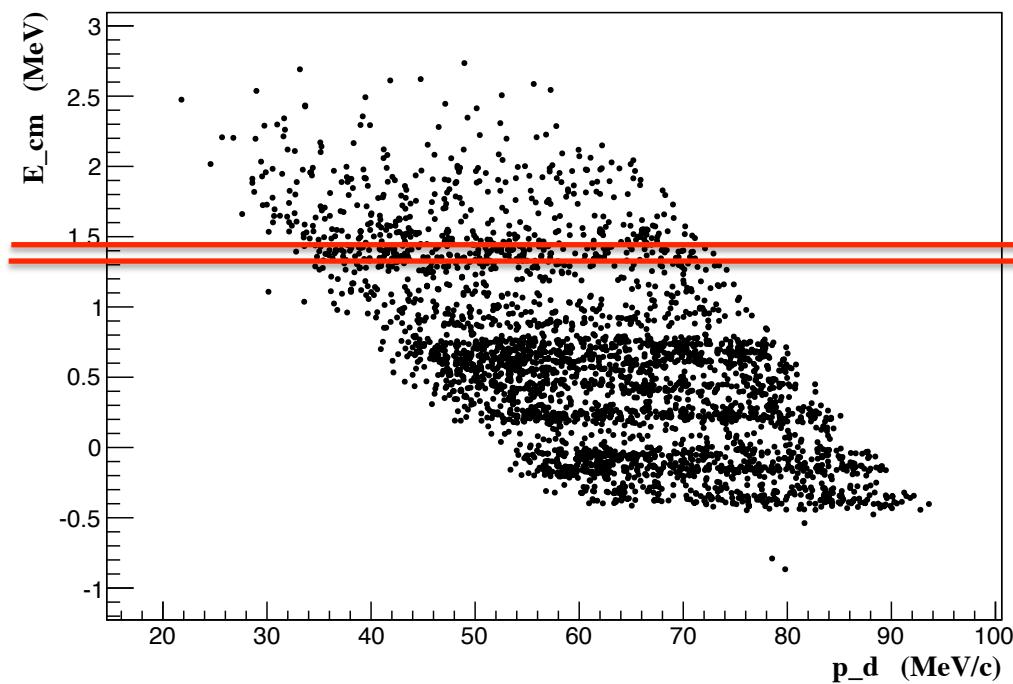

# Selection of the quasi-free mechanism

Comparison between the experimental momentum distribution and the theoretical one

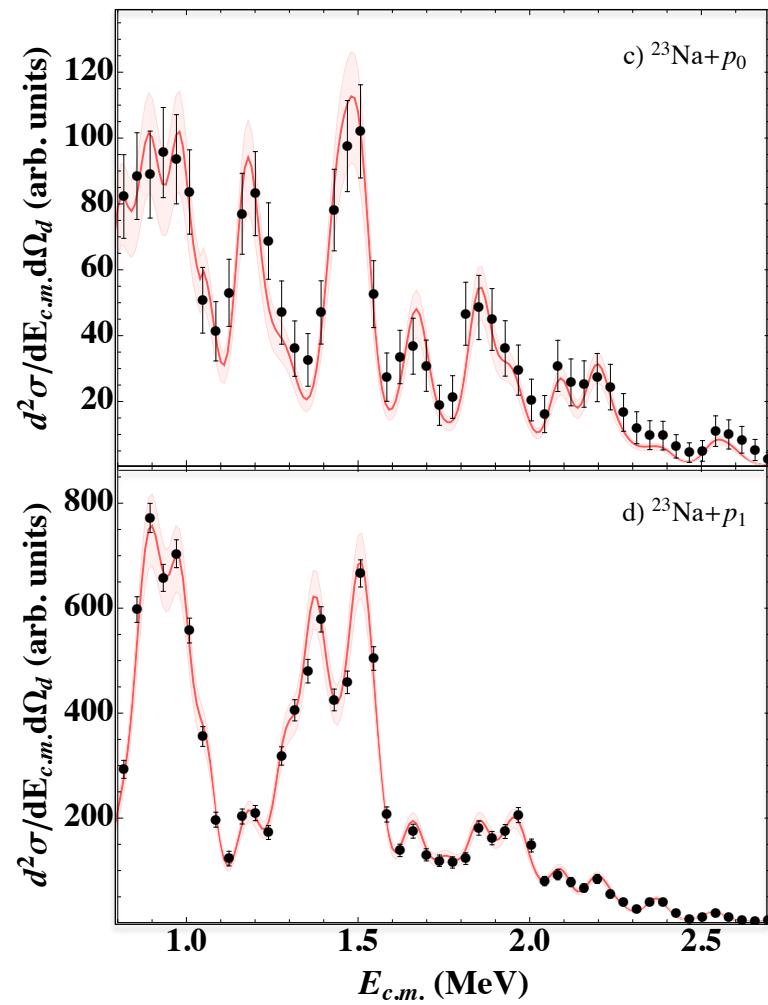

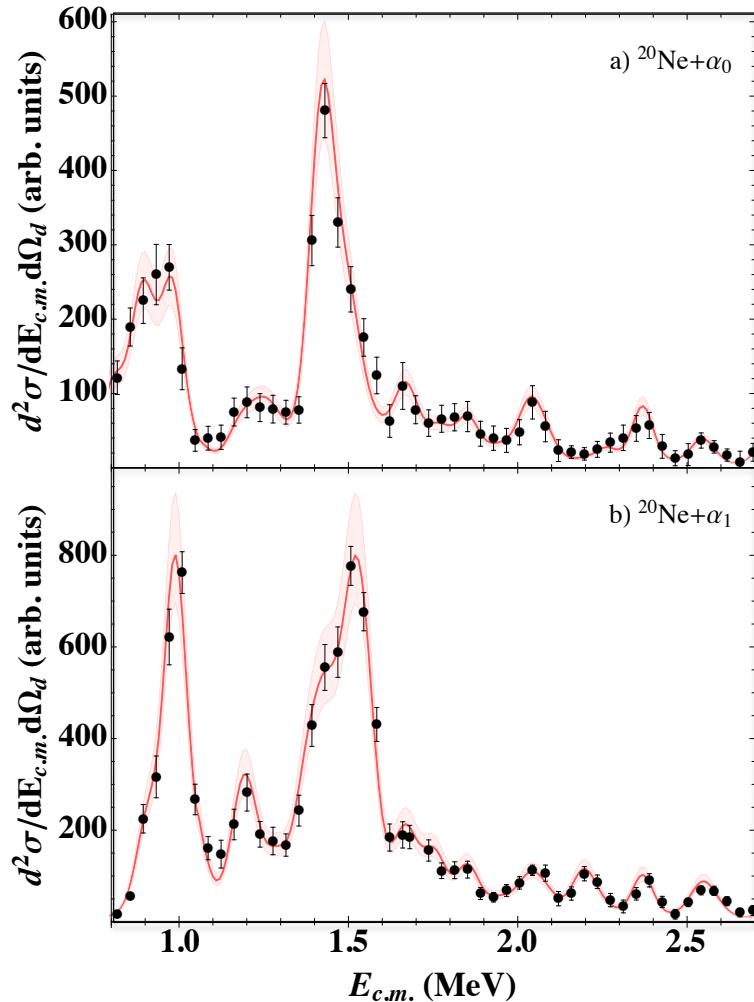

$$|\Phi(\vec{p}_d)|^2 \propto \frac{d^3\sigma}{(KF) \left( \frac{d\sigma_{^{12}C^{12}C}}{d\Omega} \right)^N}$$

Momentum distribution of d inside  $^{14}\text{N}$  from the Wood-Saxon  $^{12}\text{C}-\text{d}$  bound state potential with standard geometrical parameters  
 $r_0=1.25$  fm,  $a=0.65$  fm and  $V_0=54.427$  MeV

# Extraction of the two-body cross section

$$\frac{d\sigma_3}{dE} = KF |\varphi(p_s)|^2 \frac{d\sigma}{dE}$$

Red lines and bands: R-matrix fits for all channels at the same time

Reduced widths for known levels are fixed to reproduce their total and partial widths as in Abegg & Davis, PRC 1991

# Conclusions

THM (this holds for indirect in general) measurements are unique tools to investigate reactions or energy ranges difficult to study otherwise

Fields of interest: astrophysics, applied physics, nuclear structure, fundamental interactions

However, guidance by direct data and normalization to them is necessary not to incur in systematic errors

→ A synergic application of direct and indirect approaches is the best guarantee of accurate reaction rates for astrophysical applications

INFN, Laboratori Nazionali del Sud, Università di Catania, Italy,  
and Università di Enna "Kore", Italy

THANK YOU FOR YOUR ATTENTION!

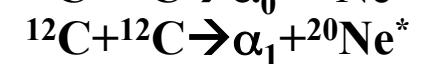

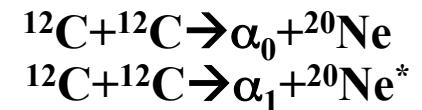

# Comparison between two-body cross sections in the astrophysical region

Further step: R-matrix fits on all channels at the same time in the full energy range of interest →

$$\frac{d^2\sigma}{dE_{xA}d\Omega_s} = NF \sum_i (2J_i + 1) \times \left| \sqrt{\frac{k_f(E_{xA})}{\mu_{cC}}} \frac{\sqrt{2P_{l_i}(k_{cC}R_{cC})} M_i(p_{xA}R_{xA}) \gamma_{cC}^i \gamma_{xA}^i}{D_i(E_{xA})} \right|^2$$

$$k_f(E_{xA}) = \sqrt{2\mu_{cC}(E_{xA} + Q)/\hbar}$$

$D_i(E_{xA})$  = Standard R-matrix denominator of four-channel formulas

Reduced widths for known levels are fixed to reproduce their total and partial widths as in Abegg & Davis, PRC 1991

**IMPORTANT:** reduced widths are the same for the extraction of the  $S(E)$  factors → From the fitting of the experimental THM cross section they can be obtained and used to deduce the OES  $S(E)$  factor.
